Ultrasound of eye - B scan

B-mode (brightness-mode) scanners are what is most often thought of when one refers to ultrasound. B-mode produces a two-dimensional reconstructed image of internal body structures based on reflected sound waves. The first commercially available handheld B-mode scanner was produced in 1963 . Around the same time, many researchers started looking into Doppler applications with ultrasound to detect blood flow as well.

Eye and Orbit Ultrasound: Purpose, Procedure, and Risks

B-scan ultrasound uses high frequency soundwaves that are transmitted from a probe/transducer into the eye. As these soundwaves strike the intraocular structures, an echo is reflected back to the probe and converted into an electrical signal. This signal is then reconstructed into a two-dimensional image on a monitor.
