Definition 1 Let $f: \mathbb{R} \rightarrow \mathbb{R}$. The Fourier transform of $f \in L^1(\mathbb{R})$, denoted by $F[f](\xi)$, is given by the integral: $F[f](\xi) := \int_{-\infty}^{\infty} f(t) \exp(-i \xi t) dt$ for $\xi \in \mathbb{R}$ for which the integral exists. We have the Dirichlet condition for inversion of Fourier integrals. Theorem 1 Let $f: \mathbb{R} \rightarrow \mathbb{R}$. Suppose that (1) $\int_{-\infty}^{\infty} |f(t)| dt < \infty$ and (2)

This chapter presents the main mathematical tools used in Fourier transform nuclear magnetic resonance (NMR) spectroscopy and in the associated signal processing. The advantage of Fourier transform spectroscopies compared to classical ones is discussed. Then the behavior of a linear system quite similar to a relaxing nuclear magnetic moment is analyzed.

Chapter 1 The Fourier Transform 1.1 Fourier transforms as integrals There are several ways to define the Fourier transform of a function $f: \mathbb{R} \rightarrow \mathbb{C}$. In this section, we define it using an integral representation and state some basic uniqueness and inversion properties, without proof.

1.1 Introduction. At the heart of Fourier acoustics is the Fourier transform which includes the concepts of the Fourier series and the Hankel transform. We present in this chapter much of the prerequisite mathematics needed to understand the concepts presented in this book. Special functions, like the Dirac delta function are crucial and provide an elegant shorthand in the mathematics.

In this chapter, we shall study some basic properties of the Fourier transform. Section 1.1 is concerned with its definition and properties in $L^1(\mathbb{R}^n)$. The case $L^2(\mathbb{R}^n)$ is considered in Section 1.2. The space of tempered distributions is briefly considered in Section 1.3.

\mathcal{F} maps $L^1(\mathbb{R}^n)$ to $C_0(\mathbb{R}^n)$ and $L^1(\mathbb{R}^n)$ to $C_0(\mathbb{R}^n)$. In particular $\|\mathcal{F}f\|_1 \leq \|f\|_1$. Thus the Fourier transform can be regarded as a map $L^1(\mathbb{R}^n) \rightarrow C_0(\mathbb{R}^n)$ where $L^1(\mathbb{R}^n)$ are the compactly supported sequences with values in \mathbb{C} , and $C_0(\mathbb{R}^n)$ are the continuous functions on \mathbb{T} with values in \mathbb{C} .

Fourier transform defined There you have it. We now define the Fourier transform of a function $f(t)$ to be $f^{\wedge}(\omega) = \int_{-\infty}^{\infty} f(t) e^{-i \omega t} dt$. For now, just take this as a formal definition; we'll discuss later when such an integral exists. We assume that $f(t)$ is defined for all real numbers t .

The operation of taking the Fourier transform of a signal will become a common tool for analyzing signals and systems in the frequency domain. The application of the DTFT is usually called Fourier analysis, or spectrum analysis or "going into the Fourier domain or frequency domain."

Short-time Fourier transform (STFT) is a sequence of Fourier transforms of a windowed signal. STFT provides the time-localized frequency information for situations in which frequency components of a signal vary over time, whereas the standard Fourier transform provides the frequency information averaged over the entire signal time interval.

The convolution theorem is a useful result of Fourier transforms that simplifies what could otherwise be a complex mathematical operation. It states that the convolution of two functions, $f(x)$ and $g(x)$, in real space is equal to the multiplication of the two Fourier transforms of these functions, $F(u)$ and $G(u)$, in reciprocal space:

Perhaps the most foundational and ubiquitous coordinate transformation was introduced by J.-B. Joseph Fourier in the early 1800s to investigate the theory of heat. Fourier introduced the concept that sine and cosine functions of increasing frequency provide an orthogonal basis for the space of solution functions.
